UI extensibility

Share code between your extensions using npm workspaces

Learn how to use npm workspaces to share code between your UI extensions.

As you build out your UI extensions, you can leverage **npm workspaces** to share code across your **app cards**, **settings page**, and **app home page**. This allows you to consolidate common logic such as formatting dates and currency, and ensure that any fixes or updates are rolled out consistently to each UI extension.

Prerequisites

Before getting started, install the latest version of the **HubSpot CLI**. In a terminal window, run the following command:

```
npm install -g @hubspot/cli
```

The CLI needs to be version `8.0.0` or later.

> You can check which version of the CLI you have by running `hs --version`.
>
> If needed, you can run the command `npm install -g @hubspot/cli@latest` to update to the latest version of the HubSpot CLI.

Project structure

The code for your card, setting page, and home page follows the same directory structure as outlined in the . The main change you'll need to make to set up code sharing between your extensions will be to add a `package.json` file at the root of your project under `src/app/`. The naming convention and scope you choose for these shared packages is entirely customizable, allowing you to use a pattern you're already comfortable with, such as `@packages/types`.

HubSpot Developers

```
└── hsproject.json
└── src/
    └── app/
        └── app-hsmeta.json
        └── package.json
        └── packages/
            └── types/
                └── package.json
                └── index.ts
            └── utils/
                └── package.json
                └── index.ts
            └── components/
                └── package.json
                └── index.tsx
        └── cards/
            └── MyCard.jsx
            └── my-app-card-hsmeta.json
            └── package.json
        └── settings/
            └── Settings.tsx
            └── settings-hsmeta.json
            └── package.json
        └── pages/
            └── Home.tsx
            └── package.json
```

Configure npm workspaces

After you create a `package.json` file in the `src/app/` directory of your project, open the `package.json` file and define the `name` and `workspaces` fields:

- `name` : the name of your project (e.g., `my-hubspot-project`).
- `workspaces` : an array that includes the UI extension directories where you plan to use your shared code, along with the directory where your shared code lives (e.g., `packages/*`).

```
  "name": "my-hubspot-project",
  "workspaces": ["cards", "settings", "pages", "packages/*"]
}
```

Create shared packages

You can use any naming convention when defining the package scope for your shared code (e.g., `@my-hubspot-project` in the examples below).

The code blocks below provide examples for defining shared `types`, `utils`, and `components` that you can then import into your UI extensions.

Types

The examples below define a simple `Money` type under `packages/types` in your project.

package.json index.tsx

```
{
  "name": "@my-hubspot-project/types",
  "private": true,
  "version": "1.0.0",
  "main": "index.ts"
}
```

Utilities

The examples below define a utility under `packages/utils` that will format data using the `Money` type from above.

HubSpot Developers

```
{
  "name": "@my-hubspot-project/utils",
  "private": true,
  "version": "1.0.0",
  "main": "index.ts",
  "dependencies": {
    "@my-hubspot-project/types": "1.0.0"
  }
}
```

Components

The examples below demonstrate a shared component that lives under `packages/components` .

package.json index.tsx

```
{
  "name": "@my-hubspot-project/components",
  "private": true,
  "version": "1.0.0",
  "main": "index.tsx",
  "dependencies": {
    "@hubspot/ui-extensions": "latest",
    "react": "^18.2.0"
  }
}
```

Add dependencies to extensions

HubSpot Developers

```
  "name": "@my-hubspot-project/my-cards",
  "dependencies": {
    "@hubspot/ui-extensions": "latest",
    "@my-hubspot-project/types": "1.0.0",
    "@my-hubspot-project/components": "1.0.0",
    "@my-hubspot-project/utils": "1.0.0"
  }
}
```

Use shared code in your UI extensions

The following code block shows how to use your shared code within one of your UI extensions:

```
import { hubspot } from "@hubspot/ui-extensions";
import { Text } from "@hubspot/ui-extensions";
import { Money } from "@my-hubspot-project/types";
import { Section } from "@my-hubspot-project/components";
import { formatDate, formatMoney } from "@my-hubspot-project/utils";

const dealAmount: Money = { amount: 15000, currency: 'USD' };

hubspot.extend<'crm.record.tab'>(({ context }) => (
 <Section title="Deal Summary">
   <Text>Amount: {formatMoney(dealAmount)}</Text>
   <Text>Close Date: {formatDate('2024-03-15')}</Text>
 </Section>
));
```

After you've added the imports of your shared code in your UI extensions, you can proceed with the next step of installing the shared packages so the project will build.

Install shared packages

HubSpot Developers

Alternatively, your shared packages will automatically be installed next time you run `hs project dev` or `hs project upload`.
